Report: How the Travlixto App Was Built

Travlixto was built as a native Android application using Kotlin and Jetpack Compose, Google's modern declarative UI toolkit. Starting from the provided mockups — Splash, Onboarding, Authentication, Home, Details, Schedule, Search, Popular Places, and Profile — each screen was implemented as an individual Compose function, keeping the visual structure and cyan brand color consistent throughout.

Build & Delivery

The project is a standard Gradle-based Android Studio project (Kotlin DSL build files, Compose BOM 2024.06, Firebase BOM 33.1.2). It was authored and organized in a development sandbox without Android SDK or emulator access, so final compilation, testing, and signing must be completed in Android Studio. Once verified, the app is packaged as a signed APK or Android App Bundle for distribution via internal testing or the Google Play Store; Firebase itself requires no separate hosting, as Authentication and Firestore are fully managed cloud services.

AI tools used

I used Claude AI to help with the firebase Authenticator set up and to understand Retrofit API since I've never used either properly. They gave a good understanding and how to implement and where I went wrong

I also used W3Schools for Kotlin reference and tutorials on new features to help make the app.

The images below are the creation of the signed apk of the Travlixto.apk app.
